MENOFIA UNIVERSITY · Faculty of Computers and Information · Java Spring, Section 2

Week 2 Task: Register it yourself

Start from: `eventia-starter.zip`, uploaded with this sheet. Unzip it and open the folder in IntelliJ. The dependencies are already in the `pom.xml`, you do not add any.

Run it once before you touch anything. It prints **5 beans** and you wrote none of them. That is your starting point.

1. Make `com.eventia.model.Reservation` with **three attributes and nothing else**: `String code`, `String email`, `int seats`. No getters, no setters typed by hand. One Lombok annotation writes all six for you, plus `toString`.

2. In `App.java` build one: `new Reservation("R-1", "a@b.com", 3)`. It will not compile. Read the error, then add **one more annotation** that fixes it, still without writing a constructor.

3. In `AppConfig`, register a `java.util.Random` as a bean with `@Bean`. You cannot put `@Component` on it, it is not your class.

4. Make `com.eventia.service.ReservationService` with `@Component` and a Lombok logger. **Do not type the logger line.** Log one confirmed reservation, and one refused because the event is full. You pick the level for the refusal.

5. In `logback.xml` put the root at `WARN` and let **only** `com.eventia.service` print at `DEBUG`, without changing any Java.

6. Run it again and look at the bean count. It should not be 5 any more.

```
./mvnw -q clean compile exec:java -Dexec.mainClass=com.eventia.App
```

On Windows use PowerShell, not `cmd`. The easiest way is the terminal inside IntelliJ.

What to hand in

Zip the project folder and upload it. Nothing else.

Delete the `target` folder before you zip, it is build output and it makes the file large for no reason.
